**Abstract:** Vitamin A deficiency is highly prevalent in India, particularly among children. The mango fruit, owing to its higher production and affordability, have potential to mitigate the disorder. Reports on the contents of vitamin A precursors and ranking among wide range of Indian mango varieties are scanty. The present study was therefore undertaken to characterize as many as 439 Indian mango varieties for their moisture, individual carotene and xanthophylls contents. The cultivars of mango fruits were sampled from different locations of the country at the level of farmers or local market and analyzed for moisture content, total carotenoids,  $\beta$ -Carotene,  $\beta$ -Cryptoxanthin, lutein and Zeaxanthin in the edible pulp. Interestingly, it was observed that 9 and 14 varieties of mangoes possessed the potential to provide 300% and 150% of RDA respectively for  $\beta$ -Carotene.  $\beta$ -Cryptoxanthin and lutein content of mango varieties was found to be in the range of 0.12-68.14 $\mu$ g/100g and 0.23-120.31  $\mu$ g/100g respectively for the edible pulp of mangoes. In our opinion, this report forms a novel attempt for a comprehensive evaluation of carotenoids content in various verities of Indian mango and could be utilized as food source for alleviating the prevalence of vitamin A deficiency in Indian population.

**Keywords:** Carotenoids content, *Mangifera indica*, RPHPLC, recommended dietary allowance, vitamin A deficiency

### INTRODUCTION

Vitamin A deficiency has been recognized as a major health issue in south Asian countries. India is reported to suffer from highest degree of clinical and subclinical VAD with 62% of pre-school

children being vitamin A deficient. About 35.3 million children in India are vitamin A-deficient followed by Indonesia (12.6 million) and China (11.4 million) [1]. Economic constraints, socio-cultural limitations, insufficient dietary intake, and poor

bioavailability/absorption are important determinants of VAD in South Asian developing countries [2]. Paradoxically, vitamin A deficiency appears to be a major issue in counties that are endowed with various  $\beta$ -Carotene-rich fruits and vegetables. Children and pregnant women are most vulnerable group for VAD, where they are living in "Poverty in the midst of plenty". VAD begins as a silent, unseen threat which if untreated can eventually rob children of their eye sight and their lives. The geriatric population in India is challenged with age-related macular degeneration (AMD) and dietary Lutein and Zeaxanthin have shown promise to combat AMD [3]. Epidemiological studies suggest that carotene rich foods may protect against many chronic diseases [4]. Carotenoids such as Lutein, Zeaxanthin, precursors of Vitamin A like  $\alpha$ -Carotene and  $\alpha$ -Cryptoxanthin are present in commonly consumed Indian foods [5, 6]. Recent studies by National Nutrition Monitoring Bureau (NNMB) indicated that, in addition to other factors, low consumption of leafy vegetables and fruits are linked to VAD in Indian population [7].

India being agriculture based country, accounts for a wide variety of fruits and vegetables cultivated across the nation. India is likely to be the most populous country by 2030, with approximately 1.6 billion people and ensuring food and nutrition security for such a large population is indeed a challenge [8]. Mango (*Mangifera indica* L.), commonly referred to as the king of the fruits, belongs to the *Anacardiaceae* family and is one of the most widely consumed tropical fruit known for its unique taste, attractive color and flavor, affordability and nutritional qualities. It is a rich source of vitamins, organic acids, carbohydrates, amino acids, phenolic acids and certain volatile compounds [9]. Many of the pharmacological properties of mango are attributable to presence of phenolic acids, due to which it can be termed as functional food. Mango has its origin from Manipur, India is the national fruit of India has been an integral part of the life and

culture since time immemorial [9]. There are over 1000 named mango varieties that are available in India, most having distinct characteristics and uses, some consumed year long as mango pickles while most others are consumed in raw form [10]. Nutrient and bioactive phytochemicals composition provides an important link for biodiversity, nutrition and health [11]. Despite India being one of the largest producers of mango, a fruit known for its therapeutic effect, information on carotenoids profile of mango varieties available in India are scanty. Thus, analytical determination and dissemination of quantitative information on nutrient and phytochemicals constituents of Indian mango varieties is necessary and important. In this context, following study was undertaken to comprehensively evaluate a large number of mango varieties available across India for their carotenoids' profile including total carotenoids,  $\beta$ -Carotene,  $\beta$ -Cryptoxanthin, lutein and Zeaxanthin.

## MATERIALS AND METHODS

Ripened fruits of four hundred and thirty nine (439 Nos.) varieties of mangoes were procured either directly from farmers or from local markets across the country. The entire range of sampled varieties were identified and authenticated by local agricultural experts and scientists. Emphasis was laid on ensuring that samples collected were ripe (ready for consumption) and undamaged as evidenced by visual inspection. Representative samples were drawn from stratified pools of each variety for evaluation of nutrient and phytochemicals content. Cleaned mangoes were weighed before further processing for separating peel, pulp and seed. Individual weights of peel, pulp and seed were also recorded.

The edible pulps of all the mango varieties were analyzed for moisture content immediately by using the thermo gravimetric method (AOAC, 2000) [12]. The remaining test portions of the mango pulp were stored at -20 °C and were analyzed for individual carotenoids content within 7 days. Carotenoids were

extracted and individual carotenoids were quantified by RP-HPLC as described previously [6]. Each analyte was determined in triplicate for each mango variety. The amount of the mango (pulp) needed to meet Vitamin A RDA (2010) was calculated using the ratio of  $\alpha$ -carotene to Vitamin A (8:1) where as for other Vitamin A precursors the ratio (16:1) was adopted (ICMR, 2010) for the assessment of Vitamin A precursors and impact of Vitamin A requirements in Indian Population [13].

**Statistical analysis:** Mean was calculated for each parameter from individual values and data represented as mean  $\pm$  SD. The variability, range and distribution of the nutrient values were analyzed and plotted by using SPSS Inc., IBM.

## RESULTS AND DISCUSSION

India being one of the largest producers of mango in the world, accounts for a very large number of cultivars of the fruit, there is scanty on nutritive value of individual varieties. Therefore in the present study, the carotenoid levels in various varieties (439) were quantified along with moisture content. Initial observations revealed that the fruit weights of different varieties were in the range of 42.19 g to 554 g. The pulp content of mango varieties was found to vary from 17.53 g in *Doodia Mamidi* to 117.23 g in *Alphonso*. The average pulp weight of the mango fruits was found to be 63.80 g. The peel content of mango varieties varied from 8.20 g in *Sora* to 55.13 g in *Prabhath Shankar*. The average seed weight of these mango varieties was found to be 22.59 g (data not shown). While pulp is the most important part of the fruit, other parts have potential to be exploited as source of bioactive components. It has been shown that mango varieties like *Alphonso* and *Rasipuri* by-products can be utilized for deriving valuable bioactive compounds such as poly phenols, carotenoids, dietary fibers and enzyme [14]. Reports have suggested that Indians did have knowledge in mango biodiversity and traditional mango products [15].

Quantitative data on carotenoids content of the tested mango varieties are presented in Table 2. Our study reveals considerable variation in both content (Total carotenoids) and composition (Individual carotenes and xanthophylls) among cultivars (Table 1). Therefore, quantitative carotenoids data for mango varieties that could be used to estimate individual carotenoids intake from mangoes that are consumed at region/local level will be useful in epidemiological studies. The total carotenoids content of mango varieties varied from 15.96 mg/100g in *Jagath Ramani* to 0.225 mg/100g in *Swarna Jehangir*. The average total carotenoids content in the mango varieties was found to be 2.07 mg/100g. There were very few studies on mango varieties grown in India with respect to total carotenoids in general and carotenoids profile in particular. Studies conducted on three mango varieties at CFTRI, Mysore, India indicated higher contents with regard to the total carotenoids [16]. A dozen varieties of mango grown in Bangladesh were reported to have lower content of total carotenoids ranging from 108  $\mu$ g/100g in *Arshini* to 444.66  $\mu$ g /100g in *Aamruapl* [17].

Earlier studies performed by our group provide data on  $\beta$ -carotene content of commonly consumed Indian foods [5,6]. Although the contents of  $\beta$ -carotene in fruit samples (mostly in the range of 0.001 to 2.95 mg/100g) were found to be significantly lower as compared to leafy vegetables, mango stood out among fruits as a rich source for  $\beta$ -carotene [5]. The present study indicates that  $\beta$ -carotene is detectable in all the varieties studied with the highest  $\alpha$ -carotene levels being found in *Swarna Butto* (11.52 mg/100g) and *Swantham* (11.51 mg/100g) followed by *Amini* (10.51 mg/100g), *Muran Dan* (10.51 mg/100g), *Anar Mulgoa* (10.22 mg/100g), and *Vasi Badami* (9.85 mg/100g). The lowest  $\beta$ -carotene content of 113.88  $\mu$ g/100g was found in *Chausa* and *Swarna Jehangi*. Data on relative contribution of  $\beta$ -Carotene to total carotenoid pools of the fruit emerging from the present study is in agreement with the study of

Mercadante and Rodriguez-Amaya [18] who have demonstrated that all-trans- $\beta$ -carotene is the most important of mango carotenoids, representing 48–85% of the total carotenoids content depending on cultivar and fruit maturity stage.

An average of 2.35mg/100g of  $\beta$ -Carotene was found among 52 fruits viz., *Shravani, Kalanji, Karutha Columban, Khaja pasand, Pargi Himayath, Pedda nelum, Alampur Banesban, Mylapuri, Gola Neek Noor, Section 19, K.O.17, Shabath bhob, Sharbati Borgin, Sora, Aryavartam Irsala, Azam Us samar, Panchavarananam, Gulab Khas, Hybert – 192, Arya Samaj, Bada – Gulabi, Vattam, Hybrid 11, Panchandan golla 132, Bombay green, Amrapali plot no 31, Kurnool mamidi, sunder shah, Hindustan Batli, Sanakulu X No.5, Chinarasalu, Dori, creeping, Surun gudi, raja pasand, Peach, Mahmood, Bombay no 1, Samar-e-behist, Ghotthi, Nelesharn x Gujarat, Almaas, Shakkargola, Asifus Samar, Tobancha, Sai Sugand, Hur, Gola Badam Model, Pairi, Olour, Yellai Mamidi, Meetha Mahmood*. Studies conducted with seven mango cultivars grown in Mexico revealed that wide variation in  $\beta$ -Carotene content [19]. Although the present study does not provide data on bioavailability of  $\beta$ -carotene content of the varieties studied, the work of Veda *et al.*, [20] clearly demonstrated appreciable bioavailability of  $\beta$ -carotene levels in common Indian mango varieties such as *Raspuri, Badami, Mallika, Mulgoa, Totapuri and Neelam*.  $\beta$ -Cryptoxyanthin, commonly found xanthophyll in fruits is a powerful quencher of the singlet oxygen. Plant carotenoids play an important role in human health as antioxidants [21]. Correlation between serum  $\beta$ -Cryptoxyanthin and circulating bone metabolic markers was found in healthy individuals upon intake of juice containing  $\beta$ -Cryptoxyanthin [22]. In addition to  $\beta$ -carotene the present study also found,  $\beta$ -Cryptoxyanthin to be present in substantial quantities in the pulp of tested mango varieties.  $\beta$ -cryptoxyanthin content of mango varieties varied from 68.14  $\mu\text{g}/100\text{g}$  to 0.12 $\mu\text{g}/100\text{g}$ . The highest  $\beta$ -cryptoxyanthin content with a value of 68.14 $\mu\text{g}/100\text{g}$  was found in *Paipasha*, followed by

in *Pairi* (56.14  $\mu\text{g}/100\text{g}$ ) and *Panakalu* (55.31 $\mu\text{g}/100\text{g}$ ). The lowest  $\beta$ -Cryptoxyanthin content of 0.68  $\mu\text{g}/100\text{g}$  was found in *Malota, Malda, Bangbella x Samae best, Almaas X Rumani, Khader, Kolan ka Goa, Shabath bhob, Neelgoa, Aman, Alphonso, Amini, T/R – 16, Turpentine, Yellow arati, Anar Mulgoa, Ambalavi, Amir pasand*. The average  $\beta$ -cryptoxyanthin in the mango varieties was found to be 4.25  $\mu\text{g}/100\text{g}$ . The esterified form as laurate, myristate, or palmitate is the primary storage form of  $\beta$ -Cryptoxyanthin in fruits and vegetables [23]. Prior to absorption,  $\alpha$ -Cryptoxyanthin esters are hydrolyzed by intestinal enzymes. The non-esterified  $\beta$ -Cryptoxyanthin has a much higher bioavailability than esterified  $\beta$ -Cryptoxyanthin, owing to the increased polarity that makes  $\beta$ -Cryptoxyanthin to be easily incorporated into micelles, for relatively efficient transport from the lumen into enterocytes [24, 25]. The conversion rate of dietary  $\beta$ -Cryptoxyanthin to vitamin A, proposed by the ICMR RDA, is the same as  $\alpha$ -carotene, i.e., 16  $\mu\text{g}$  to 1  $\mu\text{g}$  retinol, and is twice the amount of  $\beta$ -carotene, i.e., 8  $\mu\text{g}$  to 1  $\mu\text{g}$  retinol (RDA, 2012). Other studies with human subjects have investigated the Vitamin A value of  $\beta$ -Cryptoxyanthin. Indonesian schoolchildren with a marginal vitamin A status, who consumed orange fruit, containing a substantially high concentration of  $\beta$ - Cryptoxyanthin, had a greater increase in serum retinol than those who obtained more provitamin A carotenoids from vegetables [19]. Based on these findings, future investigations may challenge and improve the current knowledge of the human body's capacity to convert dietary  $\beta$ -Cryptoxyanthin to vitamin A.

An important fact emerging from the study is that 9 mango varieties namely *Suwarana Butto, Swanham, K.O.18, Amini, Muvan dan, Anar Mulgoa, Vasi Badami, Amir pasand, Motichoor* have  $\alpha$ -carotene levels of 300% above RDA with an average range of 7.865 mg to 11.53 mg. Another 14 fruits, namely *Ashquith, Bandariya, Doddia Mamidi, fajri white, Muffari, Nagin, Barbella, Pahilwan, Peta Sweet Metha, Shederija Akhadi, Anarva X Langda, Anarva, Suvarna Sindhura*

and Java with an average range of 6.998mg to 4.653mg have  $\beta$ -carotene levels of 150% above RDA. Among 439 fruits, 29 varieties namely K.0.32, Neelam Xbenishan, Navaneetam,nurjahan, Panthula Mamidi, Jehangir, Jhool, Almaas X Rumani, LARI Hyderabad 13, Rasamgola,Pasi-us-samar, Sindhura Arthi,Karanji, Nadarsah, Joger, Kandurshod siker, Surkha Culcutta, Kalaalphonso, Rajapari, Mankurad, Kallra gadda, Jong, Betchas, chitrapudi goa, lal sundari, Bombaybutta, Dashehari, Panchadharra had  $\beta$ -carotene levels of 100% above RDA with an average range of 3.234 to 4.532mg respectively.

Lutein and Zeaxanthin are the two xanthophylls which are concentrated in macula of the human eye and have been shown to protect from age related macular degeneration [26]. Global researchers have identified lack of lutein and Zeaxanthin as dietary causes in cataract and AMD related blindness. More research on the development of xanthophylls rich foods is essential to formulate therapeutic/functional foods and develop dietary strategies for the management of cataract and AMD in particular for elderly people. A typical US diet contains 1 to 3 mg/day of Lutein and Zeaxanthin, while an intake of 6 mg/day have been related to decreased risk of AMD [27]. Both Lutein and Zeaxanthin were detectable in all the mango varieties tested in the present study. Lutein content of mango varieties varied from 0.23–120.31 $\mu$ g/100. The average Lutein content in the mango varieties is 6.40 $\mu$ g/100g. The highest Lutein content with a value of 120.31 $\mu$ g/100g is present in Mango green (Unripe) followed by Paipash with 57.70 $\mu$ g/100g and Bobbili punasa with 34.12 $\mu$ g/100g. The lowest Lutein content with an average value 0.62 $\mu$ g/100g is present in Sabre, Naseem Pasand, Thambva, Podadiya, Prabbashankar kayallu. About 87 mango varieties like, Pahilwan, Peta Sweet Metha, Shams-us-samar, Rasamgola, T/R – 17, Borbacha, Cherukurasam, Rajapari Xlangda, Roos, ram phalya, rataul, ratnagiri alphonso, Bhopadiya, Narela, Malota, firangi ladwa, Gola langda, hajipur langra, Kurnool Goa, Safeda Mulgoa etc., are having Lutein content of ~ 3.5 $\mu$ g/100g.

## DISTRIBUTION OF MOISTURE AND CAROTENOIDS IN THE INDIAN MANGO VARIETIES

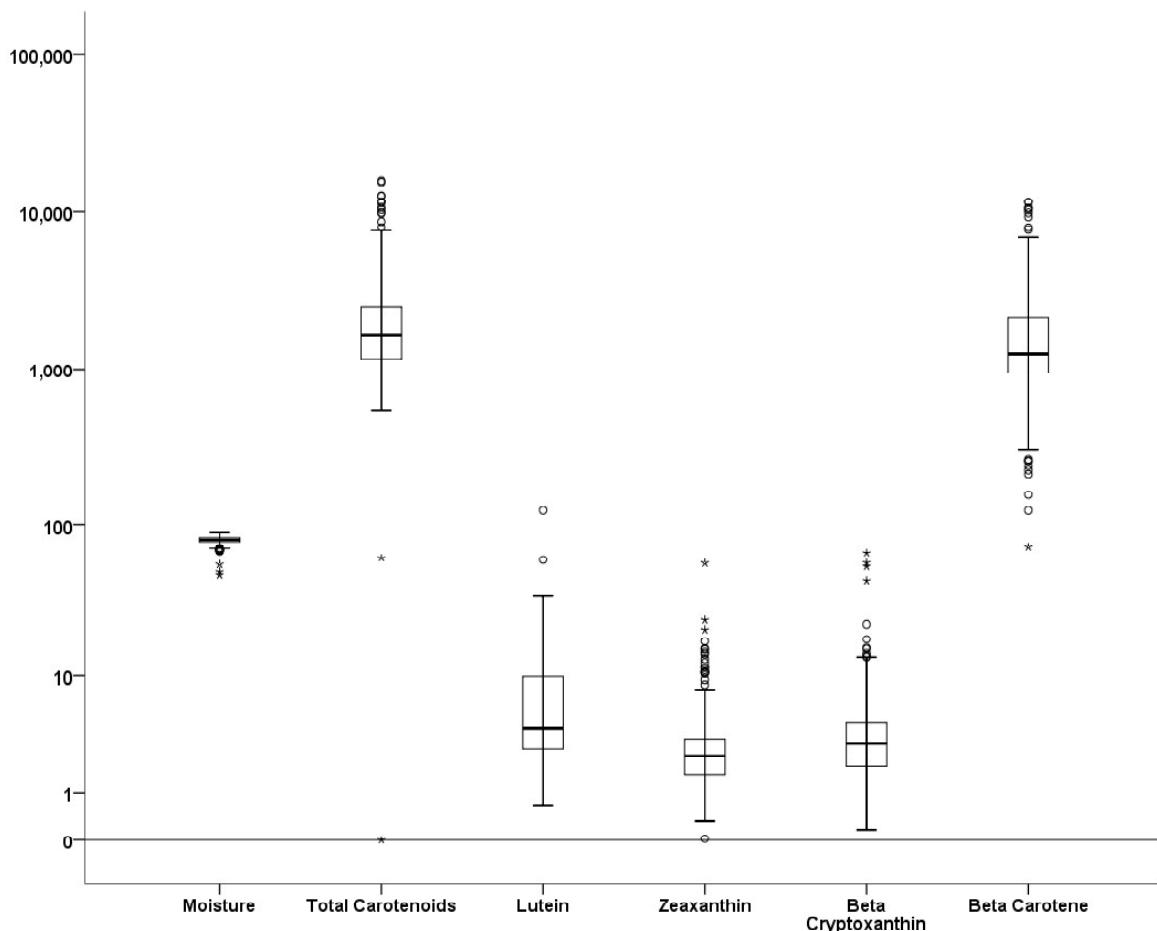

The negative and significant value of skewness (-1.867) for moisture contents indicates that the distribution frequency of moisture values are more toward the lower side than the central value. This means a large number of varieties are having moisture contents lesser than central value and only few of the varieties are having substantially higher moisture values. Significant and positive skewness values for total carotenoids (3.273), Lutein (8.572), Zeaxanthin (8.294),  $\beta$ -Cryptoxanthin (6.943) and  $\beta$ -Carotene (2.976) suggests that the distribution of the content values are comparatively more towards higher side of the central value than towards lower side of the central value. From the median, variance and range values it is evident that the proportion of individual carotenoids' content in the different mango varieties are in the order of beta Carotene>Lutein>Beta Cryptoxanthin>Zea Xanthin (**Table 1**). Positive value of the Kurtosis for individual carotenoids particularly that of Lutein and Zeaxanthin reveals that when compared to a normal distribution, the values are more clustered towards the central value. The percentile values of the moisture content suggest that more data values are distributed between 25 and 50 percentile while that of the individual carotenoids suggests that large numbers of values are distributed between 50 and 75 percentile (**Figure 1**).

Epidemiologic studies have suggested that dietary Lutein and Zeaxanthin may be of benefit in maintaining cognitive health. An examination of a relation between cognition and Lutein and Zeaxanthin concentrations in the brain tissue of decedents from a population-based study in centenarians found that Zeaxanthin concentrations in brain tissue were significantly correlated to antemortem measures of global cognitive function, memory retention, verbal fluency, and dementia

severity after adjustment for age, sex, education, hypertension, and diabetes [26]. Human studies have demonstrated the presence of Lutein and Zeaxanthin in the skin. Animal studies have provided evidence of effective protection against ultraviolet light-induced skin damage [28]. Therefore role of Zeaxanthin in human health is widening. Thus it is interesting to enumerate the food sources of Lutein and its coexistent isomer, Zeaxanthin. Present study additionally screened for Zeaxanthin in mango varieties and it is found in the range of 0.02μg/100 to 55.40μg/100g of edible pulp. The average content in the mango varieties is 2.94μg/100g. The highest

Zeaxanthin content with a value of 55.40μg/100g is found in Paipasha followed by Panakalu with 21.45 μg/100g and Dashehari with 20.8240μg/100g. The lowest Zeaxanthin content of 0.73 μg/100g was observed in *Baramasi X Max*, *Rehman Pasand*, *Mankurad*, *Zuvedrathyamamidi*, *ram phalya*, *rataul*, *ratnagiri alphonso*, *Chausa*, *Sultan US Samar*, *firangi ladwa*, *Gola langda*, *hajipur langra*, *Shendrya Mamidi*, *Mulgoa Goa black 32*, *Safeda Mulgoa*, *Dashehari Mehmooda*, *Mango Green (Unripe)*, *Raj manu*, *Intima*, *Narela*, *Burshangut*, *KO 22*, *Suwarana Butto*, *Sai Sugand*, *Intemax* etc., Around 178 mango fruits contained an average of 1.48 μg/100g of Zeaxanthin.

## CONCLUSIONS

Analytical data of moisture, Beta carotene, Lutein, Beta Cryptoxanthin and Zeaxanthin contents of commonly consumed Indian mango varieties (439 Nos.) are concurrently reported for the first time. The quantified data presented will be helpful for estimating the dietary intake of carotenoids as well as Vitamin A (retinol activity equivalents) from mango fruits in the Indian population. Since the health benefits of the reported carotenoids is well established, we opine that the data could be used for enhancing the utility of different mango varieties as a source of pro-vitamin A carotenoids to alleviate vitamin A deficiency, particularly among children. Since mango is the chief ingredient in many commercial food products such as fruit bars and juices that are abundantly and ubiquitously available in India, the nutrient values in the present report could also provide wide range of options for the selection of suitable mango varieties for food production, processing and manufacture. Although the effect of processing and shelf life on the carotenoids content need further studied, it appear that the mango-based products have potential to be utilized as source of carotenoids particularly during off seasons.

## CONFLICT OF INTEREST

Authors declare no conflict of interest.

## ACKNOWLEDGMENTS

The authors wish to thank Director, National Institute of Nutrition, Hyderabad for providing opportunity to do the work.
